ABSTRACT

A number of studies focus on the effects of open innovation on firm performance. However, in our view, previous contributions suffer from two main limitations: at first, there is still no homogeneity in the proposition of what "firm performance" is, according to extant literature. In addition, we see a heterogeneity of implications for the relationship between openness and performance, since there is still no consensus among authors on whether the relationship between openness and firm performance is positive, negative or non-linear.

We address this issue through an empirical analysis of a cross-national unbalanced panel data of European firms listed in the five major European markets in the years 2008–2013. We seek to sort the impact of the level of inbound openness, derived by the amount invested in internal development versus the external acquisition of intangible assets on firm performance according to three dimensions: economic performance, measured as the amount of firm turnover; firm financial performance, measured with shares value; and human resources performance, measured as the level of employment.

Results of panel data regression show that the effects of both internal development and external acquisition are positive and significant across different dimensions, but their output varies in terms in magnitude and distribution both variables are positively and significantly correlated with firm turnover, and that their effect on the latter is almost equal. In addition, we find that only internal development is positively and significantly correlated with the other two dimensions of performance, once we control for firm-specific time trends. Once we control for relative size of firms in the sample, we see that the effect of openness is more spread out across different class sizes, while the effect of internal development of intangibles influences the economic performance only for larger firms, and increases employment only for relatively smaller firms, while it has no effect on the financial side of performance.

Rendimiento

Una serie de estudios centrados en los efectos de la innovación abierta en el desempeño de la empresa. Sin embargo, en nuestra opinión, las contribuciones anteriores sufren sobretodo de dos limitaciones principales: en principio, todavía, no tenemos ninguna homogeneidad en lo que podemos definir como "desempeño de la empresa" basándonos en los escritos existentes. Además, notamos una heterogeneidad de conceptos y opiniones distintas sobre la relación entre apertura y rendimiento, ya que todavía no hay ningún consenso entre los autores sobre si la relación entre la apertura y el desempeño de la empresa pueda ser algo positivo, negativo o discontinuo.

Vamos así profundizando este tema a través de un análisis empírico basado en la comparación de los datos de las empresas europeas que figuran en los cinco principales mercados europeos en los años 2008–2013. Intentamos así de clasificar el impacto del nivel de apertura entrante, derivado del monto invertido para el desarrollo interno -por un lado- y la adquisición externa de bienes intangibles en el rendimiento de la empresa -en el otro- de acuerdo con tres dimensiones: Desempeño económico, medido como la cantidad de rotación de la empresa; desempeño financiero de la empresa, medido con el valor de las acciones; desempeño de los recursos humanos, medido como el nivel de empleo.

* Corresponding author.

E-mail address: federico.moretti@unipv.it (F. Moretti).

Los resultados de la elaboración de los datos de nuestro panel muestran que los efectos tanto del desarrollo interno como de la adquisición externa son positivos y significativos en varias y distintas dimensiones, pero su producción puede variar en términos de cantidad y distribución. Ambas las variables se correlacionan positivamente y significativamente en cuanto a la rotación de la empresa y su efecto sobre el último es casi lo mismo. Además, encontramos que solo el desarrollo interno se correlaciona positivamente y significativamente con las otras dos dimensiones del desempeño de la empresa una vez que controlamos las tendencias de tiempo específicas de la empresa misma. Una vez que controlamos el tamaño relativo de las empresas consideradas, nos damos cuenta que el efecto de la apertura está más extendido en diferentes tamaños de clase, mientras que el efecto del desarrollo interno de intangibles influye en el rendimiento económico solo para las empresas más grandes y aumenta el empleo solo para las empresas relativamente más pequeñas; mientras que no tiene ningún efecto en el lado financiero de ningún tipo empresa.

Introduction

Open innovation (OI) is one of the hottest topics in management literature in the past decade. According to Scopus dataset, ever since the introduction of the term in 2003, over 3600 articles have been published on the topic. Following the original definition, OI represents a new model to pursue activities where “[...] firms commercialize external (as well as internal) ideas by deploying outside (as well as in-house) pathways to the market”. (Chesbrough, 2003). Enkel, Gassmann, and Chesbrough (2009) distinguish three dimensions of open innovation: “outside-in”, “inside-out” and “coupled”. In particular, the outside-in (inbound) process aims at enriching the company knowledge capital by internalizing externally developed technologies. Firms search for valuable sources of knowledge in their environment, leveraging on potential sources of ideas arising from other players, i.e. suppliers, customers, competitors or universities. Drivers of acquisition of external assets include lower cost of development, lower risks and faster time-to-market (Wallin & Von Krogh, 2010).

Building on the resource-based view of the firm (Barney, 1991), We join the current debate in OI literature by seeking to answer to the following question: *How is inbound openness related with firm performance?*

So far, a number of studies focused on the effects of OI on firm performance (Chiang & Hung, 2010; Hung & Chou, 2013; Lichtenhaler, 2009). However, OI literature is yet to find consensus in defining the determinants of openness, as well as in sorting its effect on performance. Extant studies present three main limitations in determining such relationship: first, we believe there is a bias in the measurement of firm level of openness in extant studies, since they mostly rely on self-reported measures of openness derived from secondary data. In addition, there is no consensus in the definition of what “firm performance” is in open innovation studies. Finally, results of extant studies on the relationship between inbound openness and performance are heterogeneous: multiple authors argue the presence of a positive relationship between openness and performance (Nitzsche, Wirtz, & Goettel, 2016; Rass, Dumbach, Danzinger, Bullinger, & Moeslein, 2013), while others argue there is a negative or non-linear relation between such variables (Laursen & Salter, 2006; Love, Roper, & Bryson, 2011; Suh & Kim, 2012).

We seek to contribute to extant literature by proposing an empirical analysis of the effects of openness – focusing on the nature of acquired intangible assets versus internally developed assets – on firm performance, measured according to three dimensions: (1) Economic performance – through the value of turnover; (2) Financial performance – the value of firm stock prices; and (3) Human capital performance – the level of firm employment. To do so, we use an unbalanced panel data of 329 European companies

listed in the five major markets – United Kingdom, Germany, France, Italy and Spain, over the period 2008–2013.

Results show that the effects of both internal development and external acquisition are positive and significant across different dimensions, but their output varies in terms in magnitude and distribution: both variables are positively and significantly correlated with turnover, and their effect is almost equal. In addition, we find that only development is positively and significantly correlated with the other two dimensions of performance, once we control for firm-specific time trends. Once we control for relative size of firms in the sample, we see that the effect of openness is more spread out across different class sizes, while the effect of development of intangibles influences the economic performance only for larger firms, and increases employment only for relatively smaller firms, while it has no effect on the financial side of performance.

The structure of the paper is the following: in the next paragraph, we will briefly review the OI literature to sort out how performance is measured by extant contributions and the direction of the relationship between openness and performance proposed by scholars. Then, we introduce the research design and methodology used in our study. In the findings section, we present the results of the econometric analysis. Finally, we list the article's contributions and implications for academics and professionals in the field, we address the limitations of the study and include suggestions for further research.

Literature review

Open innovation and performance

How is open innovation measured?

Ever since the introduction of the term “open innovation” (Chesbrough, 2003), a number of studies focused on the effects of “openness” on firm performance. The seminal contribution in this OI topic is Laursen and Salter's (2006) article, where the authors address the role of openness in determining firm's innovation performance. They introduce two variables: *search breadth* – the number of external sources the firm relies on in conducting innovation – and *search depth* – the extent on which firms deeply rely on each of these sources. They operationalize the two measures by analyzing the level of interaction firms have with various categories of external actors, including: market sources, institutional sources, specialized sources, or other sources. They find that both indicators have a curvilinear relationship with innovation performance.

The same indicators have been widely adopted by subsequent studies (including Bogers & Lhuillery, 2011; Chiang & Hung, 2010; Vahter, Love, & Roper, 2014), becoming the *de facto* standard measures to evaluate openness.

These indicators bring an effective and comparable measure to evaluate the firm level of openness, i.e. the organizational propensity toward the external environment. However, they are self-reported and subjective, thus failing to consider the actual investments in external assets conducted by the firm. So far, extant literature has focused on the propensity to cooperate with various stakeholders, without measuring the value of such transactions. In our view, more objective measures are required to evaluate the impact of acquired assets over performance. Since the choice of development of assets or their acquisition represents alternative choices, such measures should allow for comparisons between the effects of externally acquired and internally developed assets on performance.

How is firm performance measured?

Starting from [Laursen and Salter's \(2006\)](#) contribution, a number of studies have tried to address the relationship between openness and performance. However, various authors have so far used the same label – performance – to measure different dimensions such as: firm's performance ([Zubielqui, Jones, & Lester, 2016](#); [Rass et al., 2013](#)), Research & Development (R&D) performance ([Suh & Kim, 2012](#)), firm's success ([Nitzsche et al., 2016](#)), firm growth ([Love et al., 2011](#)), innovativeness/innovation performance ([Chen, Chen, & Vanhaverbeke, 2011](#); [Egbetokun, 2015](#); [Spithoven, Frantzen, & Clarysse, 2010](#)) and product/NPD performance ([Gesing, Antons, Piening, Rese, & Salge, 2015](#); [Praest Knudsen & Bøtker Mortensen, 2011](#)).

We list the number of extant quantitative studies which address the relationship between openness and performance – with particular attention to the variables used in the analysis – in [Table 1](#).

We argue that extant contributions present two main limitations: sample specific restrictions and the definition of the output “performance” variable.

As regards the first issue, all the contributions presented in [Table 1](#) use country or sector-specific samples. While this choice favors the recognition of specific patterns of openness, it does not allow confrontation of results across various contexts, thus failing to address the existence of cross-national or cross-sectoral patterns over time. In addition, much literature focuses on various “innovation-related” measures as the performance output, including scale measures for innovation performance ([Cruz-González, López-Sáez, Navas-López, & Delgado-Verde, 2015](#); [Pullen, De Weerd-Nederhof, Groen, & Fisscher, 2012](#)), continuous measures of innovation outputs, such as the number of new or significantly improved products ([Hwang, Kim, & Kim, 2009](#); [Mention, 2011](#)), or percentage measures, such as the share of sales from innovative products/services ([Chen, Vanhaverbeke, & Du, 2016](#); [Gesing et al., 2015](#)). While these measures provide objective indicators of the output of innovation efforts put through by companies, they do not directly address the effect on firm overall performance: using ratios of innovation over firm revenues does not guarantee that the firm will experience an increase in the latter, since the increasing incidence of innovation may come at expenditure of overall sales results.

To avoid distortion of results, we rely on objective and comparable performance measures of firm performance, namely firm sales, shares value and employment levels.

Openness and performance

OI literature is yet to find consensus on the openness – performance relationship. In the next paragraphs, we review significant extant contributions in the field.

Positive effects

[Chen et al. \(2011\)](#) show that both scope and depth of openness have a positive effect on the company's innovation performance. Similarly, [Pullen et al. \(2012\)](#), study the effects of firm network characteristics on innovation performance and find that goal complementarity is positively related to innovation performance. [Rass et al. \(2013\)](#) posit a positive relationship between the implementation of OI instruments and performance, and a positive relationship between the former and firm social capital. Results show that firm social capital acts as a positive moderator, positively influencing firm performance in the implementation of OI practices. [Gesing et al. \(2015\)](#) address the effects of governance modes and collaboration types on firm NPD performance, measured as the share of revenues from products that are new to the firm and the share of revenues from products that are new to the market. They find that formal collaborations with both market-based and science-based partners show a stronger positive and significant effect on revenue shares from new-to-the-firm and new-to-the-market products compared to informal collaborations. [Egbetokun \(2015\)](#) finds that the breadth of firms' network portfolio – the number of external knowledge sources – has a positive effect on both the firms' overall innovation and product innovation performance. In addition, the variety of informal collaboration has a positive impact on firms' innovativeness, while the variety of formal arrangements has a minor impact, as it only partially increases the overall innovation performance. [Nitzsche et al. \(2016\)](#) show that absorptive capacity, open culture, connectivity, strategic and structural flexibility all have a positive and significant effect on firm's innovation success.

Negative and non-linear results

[Suh and Kim \(2012\)](#) study the effects of four different type of collaboration activities – in-house R&D, technology acquisition or licensing, R&D collaboration and networking – on firm R&D performance, measured in terms of product/service innovation, process innovation and patents produced by firms, find that non-collaboration (in-house R&D) is an efficient strategy, while networking is the most inefficient strategy when considering all innovation outputs. Again, [Laursen and Salter \(2006\)](#) find that both search breadth and depth have an inverted U-shaped relationship with innovation performance. Similarly, [Garcia Martinez, Zouaghi, and Sanchez Garcia et al. \(2017\)](#) find an inverted U-shape correlation between the impact of alliance portfolio diversity on firm incremental and radical innovation performance. [Love et al. \(2011\)](#) find that firms' internal organization, the presence of external public support and increasing competition, and the creation of ties with commercial laboratories have a positive effect on the firm innovative performance – innovative sales – while increasing openness is positively but non-significantly related with innovation.

Summary

In short, extant OI literature has so far focused on defining the level of openness of the company – measured through the extent of relationships with external counterpart, failing to consider the value of the acquired assets, and their effects of performance in comparison with the development of the same products on performance. In addition, while the use of “innovation” related indicators as the output of the innovation process provides a useful indicator on the success of innovation-related activities, it does not tell us how such output influences firm's overall performance, i.e. revenue growth. Finally, we see heterogeneous views in defining

Table 1

Extant literature contributions on openness and performance.

Authors	Year	Sample	Dependent variable	Independent variables	Control variables	Moderating variables
Hwang, J; Kim, E; Kim, S	2009	- Large-scale survey - 157 OSS Korean company - 91 respondents, 86 accepted - Logistic regression	1. Technologically new product innovation, 2. Technologically improved product, 3. Technological process innovation	1. Total network (TOTALNET), 2. Domestic network (DOMNET), 3. Global network (GLOBNET), 4. State-Supported Network (STATESUP), 5. Outside Developer Network (COMMU), 6. Code Developer Weight (COREDEV), 7. Market Structure (CR3), 8. Age (AGE), 9. Size (SIZE and SIZE ²)		
Stam, W	2009	- Large-scale survey - OSS firms in the Netherlands - 125 firms involved, 121 responses from 90 firms received (72% response rate)	1. Innovative performance – n. of new products introduced by the firm 2. Financial performance – self-reported measures of firms' financial performance relative to competitors: sales growth, market share, gross profits, and net profit margin.	1. Community participation – 5-point Likert scale 2. R&D Intensity – share of R&D investments over previous years' sales	1. Firm size – log of Full Time Employees 2. Firm age – log of years	
Wincent, J; Anokhin, S; Boter, H	2009	- Focus on Swedish small-firm networks - 53 networks sample - Industries: engineering, food, health, tourism, wood, telecommunications, IT	1. Network innovative performance, 1–7 Likert Scale	1. Network continuity (% of directors with >1-year continuity)	1. Financial indicators, 2. Size of board, 3. Network age,	3. OSS Specialization – % of revenues generated from OSS 4. OSS Projects – n. of projects 5. Self-initiated OS projects – % of projects started from the focal firm
Chiang, YH; Hung, KP	2010	- Large-scale questionnaires - 800 randomly selected Taiwanese electronic product manufacturing companies - 220 valid responses (27%) in phase 1. - 184 effective responses (23%) after phase 2	1. Incremental innovation performance 2. Radical innovation performance	1. Search breadth and depth	1. Market potential 2. Technological turbulence 3. R&D intensity 4. Company size (as a surrogate)	1. Network size (n. of firms in the network each year)

Authors	Year	Sample	Dependent variable	Independent variables	Control variables	Moderating variables
Faems, D; de Visser, M; Andries, P; Van Looy, B	2010	- Community Innovation Survey, 2005 - 2075 Belgian manufacturing firms, 888 respondents (42.8% response rate). - 526 selected firms in the final sample - CIS dataset	1. Diversity of Technology Alliance Portfolio	1. Internal innovation efforts, 2. Product innovation performance, 3. Financial performance, 4. Personnel costs in value added, 5. Profit margin	1. Industry, 2. Firm size,	3. If the firm is part of a divisional entity, 4. Past financial performance
Spithoven, A; Frantzen, D; Clarysse, B	2010	- Two stratification variables: (1. the number of employees (as the average of 1998, 1999, and 2000) as an indication of size; and (2) the sector the enterprise belonged to - Belgium - 4482 firms sample, 2035 responses were received, containing both innovating (1310) and non-innovating (725) firms - 1987 firms final sample	1. Research intensity (LRDI) – log of R&D/Sales; 2. Innovative revenue (LIREV) – log of new or innovative products/Sales; 3. Growth in revenue (GREV) – logSales ²⁰⁰⁰ – logSales ¹⁹⁹⁸ .	1. Knowledge externalities (KEXT) – importance of different interfirm linkages (KEXT _{if}) and inter-organizational linkages (KEXT _{io}) 2. Research cooperation (COOP), dummy variable of interfirm cooperation (COOP _{if}) and inter-organizational cooperation (COOP _{io}) 3. Appropriability (APPR), dummy variable measuring the degree on which the firm pursues strategic protection	1. CRES – complex research, ratio between information sourced from universities, government and conferences over all information sources 2. PROC – dummy variable for process innovation 3. LHEI – log of share of employees with higher education 4. LEXI – log of share of exports over revenues 5. LSIZE – log of number of employees	3. LHEI – log of share of employees with higher education 4. LEXI – log of share of exports over revenues 5. LSIZE – log of number of employees 6. GRMS – dummy variable for “mother” or “subsidiary” firm 7. Industry-specific dummy variables, five sectors: - ISUP – supplier-dominated - ISCL – scale-intensive - ISPS – specialized suppliers - ISCB – science-based - IINF – information intensive 1. Appropriation, for both product and process innovation;
Bogers, M; Lhuillary, S	2011	- Swiss innovation survey, 1991–1993 - 659 observations	1. Product innovation-related variables (R&D Prod, Manufacturing Prod, Marketing Prod) 2. Process innovation-related variables (R&D Proc, Manufacturing Proc, Marketing Proc)	1. Customers, Suppliers, Competitors, Group members (part of the same conglomerate), 2. PROs (including universities of applied sciences, universities and public research institutes) 3. Consulting (also including private research institutes), for both product and process innovation.	2. Size; 3. Group;

Authors	Year	Sample	Dependent variable	Independent variables	Control variables	Moderating variables
Mention, AL	2011	- CIS survey, years 2002–2004 - 1052 service firms in Luxembourg	1. Innovation novelty – binary variable. Its value is 1 when firms do introduce innovations that are new to the market and is worth 0 when innovations are only new to the firm.	1. Co-operation practices: market-based, science-based, intra-group co-operation and co-operation practices.	4. Price competition; 5. Non-price competition; 6. Duration of innovative project; 7. Financial constraints; 8. Diversification; 9. Industry	
Pullen, AJJ; de Weerd-Nederhof, PC; Groen, AJ; Fisscher, OAM	2012	- 751 Dutch companies in medical devices (complete population) - up to 250 full time employees - 105 companies identified - 97 available for study - 60 final sample, response rate 61.9%	1. Innovation performance – 5 items measured on a 7-point Likert scale	Each type of co-operation is a binary variable and receives the value one if co-operation has occurred with at least one partner of the group. Network characteristics – 1. Goal complementarity, 2. Fairness trust, 3. Reliability trust, 4. Resource complementarity and 5. Network position strength	1. Goal complementarity, 2. Fairness trust, 3. Reliability trust, 4. Resource complementarity and 5. Network position strength	
Segarra-Cipres, M; Bou-Llusar, JC; Roca-Puig, V	2012	- Spanish survey on business strategies (ESEE) 2003–2006 - Two groups: 1. Firms with more than 200 employees, and 2. Firms with 10 to 200 employees - 2.188 firms surveyed - 1277 firms sample, of which 362 innovative - PITEC dataset	1. Firm's innovation outcome (RDO) – N. of new products, patents and utility models registered by the firm	1. Contribution of external sources – technological alliances with customers, suppliers, competitors and universities, joint ventures and hiring R&D employees with and without R&D experience	1. Firm size (LGS) – log number of employees, 2. Firm's age (LGA) – log of years, 3. Mean R&D in the last two years (MRDO)	
Barge-Gil, A	2013		1. Percentage of sales obtained in the last year of the period of analysis, from products new to the market, introduced in the previous three years (LNEWMK)	Openness strategy – 4 dummy variables:	1. Firm size	

Table 1
(Continued)

Authors	Year	Sample	Dependent variable	Independent variables	Control variables	Moderating variables
Berchicci, L	2013	- Spanish manufacturing firms - 2004–2008 - Surveys of Italian Manufacturing firms - 1992–2004 original sample, 2001–2004 observations considered for analysis (covering 1998–2003) - 8969 observations (and 6872 firms) - Final sample of 2905 observations (and 2537 firms)	1. Share of innovative sales – share of turnover from new or significantly improved products. Percentage value	1. Closed – no collaborative or inbound OI links 2. Semi-open – new products were obtained mainly by the enterprise on its own 3. Open – new products were achieved mainly through cooperation with other organizations 4. Ultra-open – new products are the result predominantly of the efforts of third parties	2. R&D intensity 3. Sector 4. Export behavior 5. Obstacles to innovation 6. Belonging to a group 7. Market share 8. Appropriability conditions 1. Size – total number of employees. Log function.	
Hung, KP; Chou, C	2013	- Taiwanese high tech manufacturers - Online questionnaire - 791 companies selected for analysis - 176 responses (22.3% response rate)	1. Firm performance – firm's Tobin q: ratio of firm market value to the replacement cost of its assets	1. External R&D – percentage of outsourced R&D activities over total R&D activities. Percentage value. 2. R&D capacity – number of R&D employees over total n. of employees	2. Age – total number of years. Log function. 3. Export – dummy variable for firm exporting activities. 4. Wave 2004 – dummy variable for firms included in the 2004 survey.	
Roper, S; Vahter, P; Love, JH	2013	- Irish Innovation Panel (IIP) - 1994–2008 - USPTO database	1. Proportion of plants' sales derived from products that were either newly introduced or improved during the previous three years. 2. Product innovation dummy 1. Invention output – average number of patents granted over a three-year period	1. Internal R&D effort – ratio between company R&D expenditure over sales. 2. Technological turbulence – change rate of technology used in the business 3. Market turbulence – speed of change in customer needs and preferences in competitor actions	1. Industry sectors – dummy variables for sectors (chemical & pharmaceuticals, Mechanical and electric equipment, Semiconductors, and Electronics) 2. Size – number of employees. Log measure	
Caner, T; Sun, J; Prescott, JE	2014			1. Measures of the breadth of innovation linkages (based on Laursen & Salter, 2006)	1. Therapeutic area diversity – 22 therapeutic areas Herfindahl index measure.

the relationship between openness and performance, since the multiple works show that openness has beneficial effects on performance, while other studies argue that the relationship is negative, or rather non-linear. Hence, we seek to contribute to extant literature by proposing an empirical analysis of the effects of openness – focusing on the nature of acquired intangible assets versus internally developed assets – on performance, measured in terms of overall sales, firm shares value, and the level of employment. To do so, we use an unbalanced panel data of 329 European companies listed in the five major markets – United Kingdom, Germany, France, Italy and Spain, over the period 2008–2013. Details about the research design are presented in the following section.

Research design

Sample

The empirical analysis relies on a panel regression analysis. The data collection process consisted of two main steps. First, a preliminary analysis was conducted on all companies listed on stock market exchanges (London, Frankfurt, Paris, Milan and Madrid) of the five largest European countries. All these countries have adopted IFRS (International Financial Reporting Standards) provisions, hence the data is assumed to be comparable.

The data collection process started with the collection of all 2178 companies listed on the abovementioned Stock Exchange markets for fiscal year 2008. From this first group, we excluded all the companies that did not provide financial information using IAS/IFRS principles. Then we continued excluding firms that did not meet our selection criteria: *identifiability, control and the existence of future economic benefits*. Moreover, all the companies involved in financial services were excluded from the sample.¹ The same collection procedures have been accepted in previous studies (Denicolai, Ramirez, & Tidd, 2014; Denicolai, Cotta Ramusino, & Sotti, 2015; Denicolai, Ramirez, & Tidd, 2016). From the initial sample, we were able to select 328 companies following all the eligibility criteria. We extended the original sample by including the following years, up to 2013. The final sample consists of 328 companies over 2008–2013, thus 1968 firm-year observations. From this value, we subtracted a number of companies which have been removed from listing or acquired in the reference period. The final sample is an unbalanced panel data consisting of 1896 firm-year observations. Country and industry distribution of the sample are presented in Tables 2 and 3. We complemented the data with the extraction of the same dataset using Bureau van Dijk's ORBIS Software.

Measures

Dependent variable

We adopted three different indicators to express performance: (1) economic performance, measured through firm turnover, in logarithmic form (TURN); (2) financial performance, measured through the value of shares at the end of each year included in the sample (SHARES); and (3) human capital performance, measured through the number of employees and full-time equivalents reported at the end of each year included in the sample (EMPL).

Independent variables

Independent variables considered in the model include internally generated intangible assets, externally acquired intangible assets

¹ Because of the composition of their intangible assets, almost entirely externally generated and not providing any value added in terms of innovation.

and dummy variables to indicate the specific types of assets the company invested into.

Internally developed intangible assets (INT IA), include intangibles that arose from internal activities during the fiscal year considered, besides goodwill. Externally acquired intangible assets (EXT IA), conversely, include all externally generated intangible assets, both singularly acquired and or acquired as part of a business combination. For both variables, we use the logarithmic value of the amount spent by the firm, in Euros.

Control variables

Finally, we included control variables, namely industry effects and country effects through, using dummy variables. In addition, we controlled for innovation propensity of firms, expressed as the logarithmic value of amount of R&D expenditure reported at the end of each year included in the sample, in Euros. A summary of the variables used is presented in Table 4.

Empirical strategy

The identification strategy is based on panel data regression where we are able to control for firm-level fixed effects and firm-specific linear time trend and on a GMM-system estimator (Blundell & Bond, 1998).

Our baseline empirical specification is the following:

$$\text{Perf}_{ijt} = \beta_0 jkt D_{kjt} + \beta_1 OI_{it} + \beta_2 X_{it} + \varepsilon_{it} \quad (1)$$

where D_{kjt} are sector (j) – country (k) – year (t) dummies, i.e. triple interactions of these variables; OI_{it} is our variable of interest, that is the amount of money invested in OI practices by firm i in year t and X_{it} is a vector of time-variant firm-specific controls.

In our baseline specification (1) we are not able to control for firm level time-invariant heterogeneity that could affect performance and OI practices at the same time. In order to include these factors, we rely on a second specification where we add firm-specific Fixed Effects (FEs) and year dummies:

$$\text{Perf}_{it} = \alpha_{1i} D_i + \tau_t + \beta_1 OI_{it} + \varepsilon_{it} \quad (2)$$

In this specification, the identification of our parameter of interest β_1 relies on within-firm variation in OI over time (i.e. firms are allowed to start from different intercepts). FEs allow us to control for time-invariant unobserved heterogeneity which might affect performance.

We also estimate a more demanding specification including both firm specific intercepts and firm specific time trends, allowing them to follow different trends in the outcome variables, which is:

$$\text{Perf}_{it} = \alpha_{1i} D_i + \tau_t + \beta_1 OI_{it} + \beta_2 (D_i * t) + \varepsilon_{it} \quad (3)$$

where the β_3 s are the firm-specific linear time trends.

This may address the concern that firms who saw an improvement in performance associated to an increase in OI activities may have been already on an increasing trend before the investments in OI practices.

Finally, we include a quantile regression analysis in order to check for differences in the effect of OI at different percentiles of the outcome variables.

Findings

Descriptive results

Table 5 shows the summary statistics of the variables used in the econometric analysis. In particular, firms in the sample spend, on average, 36 million Euros per year in development of intangible

assets and 52 million Euros per year in acquisition of intangible assets over the 2008–2013 period. As regards dependent variables, firms in the sample have an average turnover of 3.9 Billion Euros on average, employ 16.800 full-time personnel per year and have an average stock price of 17.77 Euros over the selected period.

Regression results

The following tables ([Tables 6–8](#)) show the results of the econometric models used in the study. All tables consist of two panels. Panel A reports the results using the expenditure in internally generated intangible assets and panel B those using expenditure in externally acquired intangible assets. Column (1) presents the estimates of the specification with triple interactions ([Eq. \(1\)](#)), column (2) shows the estimated values from the equation with firm-specific FE, in column (3) firm-specific time-trends are added to the specification in column (2). Finally, in columns (4)–(6) we present estimates for the quantile regressions at the 50th, 80th and 20th percentiles.

[Table 6](#) investigates the effect of expenditure on intangible assets on firms' turnover.

Results in Column (1) show that both development and acquisition of intangible assets is significantly correlated with turnover (0.095, p -value < 0.001 and 0.127, p -value < 0.001, respectively). If we assume firms are homogeneous, it seems that intangible assets generate positive results on turnover, irrespective of their source. Specifically, the acquisition of external intangible assets generates a *vis-à-vis* greater effect on the dependent variable. The argument is aligned with the finding of positive effects of openness – measured as the extent of acquisition of external intangible assets (i.e. [Chen et al., 2011](#); [Rass et al., 2013](#)).

Adding controls for firm fixed effects and year dummies in column (2), results still show a positive and significant correlation for both asset development and acquisition with turnover (0.069, p -value < 0.001 and 0.047, p -value < 0.001, respectively). By controlling for firm heterogeneity, results show that both development and acquisition of intangibles have a positive effect on turnover, and that the effect of the former exceeds the latter: a 1% increase in expenditure for development generates a 0.069% increase in turnover, while a 1% increase in expenditure for acquisition generates a 0.043% increase. While the argument is still aligned with the positive effect on turnover generated by inbound openness, results in this specification show that the degree of incidence is *vis-à-vis* lower than the one generated by development.

To address this issue, we control for the presence of firm-specific time trends in column (3). Again, results return a positive and significant correlation with turnover for both development (0.025) and acquisition (0.026), both significant at the 10% level. By isolating the effects of firm-specific time trend, we see that external assets have a marginally greater effect on turnover than internally developed assets: a 1% increase in the former leads to a 0.025% increase in turnover, while a 1% increase in the latter leads to a 0.026% increase in turnover. Results show that positive effects are consistent throughout the specifications, and their influence on the dependent variable, once we add controls, is almost equal.

For further specification, we added quantile regressions to verify whether there are differences in magnitude when compared to firm size. Results in column (4)–(6) show that the effects of development are positive and consistent for larger firms – in the 50th and 80th percentile of the sample – while for relatively smaller firms they are not. In contrast, the positive relationship between acquisition of intangibles and turnover is consistent throughout size classes, with a marginally greater effect for firms in the 50th percentile (0.024, p -value 0.001) than in the 20th and 80th percentile (0.017, p -value 0.001 and 0.0014, p -value 0.01, respectively).

In this light, we argue that asset acquisition (i.e. increasing inbound openness) generates positive results on firm perfor-

mances, irrespective of their size, while development generates positive results (an increase in sales) only when companies are sufficiently large to exploit the outcomes of internal R&D. This, we believe, confirms that internal and external intangible assets are complements, rather than substitutes ([Denicolai et al., 2016](#)).

In [Table 7](#) we repeat the same analysis with a different dependent variable, stock prices. Results in column (1) show a non-significant relationship between development of intangible assets and financial performance (shares value), and a positive relationship between acquisition and the dependent variable (0.075, p -value < 0.1). By isolating the effects of sector, country and year specification, the expenditure on development of internal intangible assets does not appear to be correlated with financial performance, while expenditure on acquisition seems to be positively correlated with an increase in stock prices.

In column (2), results for both variables are both positive and consistent (0.067 and 0.045, respectively). Both results are consistent at the 5% level.

When controlling for firm-specific time trends in column (3), results show contrasting results to column (1): development is positively associated with firm stock price (0.066), and the relationship is consistent at the 5% level. In contrast, the effect of acquisition is negative (−0.007), although close to zero and non-significant.

Quantiles in column (4)–(6) show that development is not significantly related with share values across all groups, while asset acquisition has a positive and significant effect for relatively larger firms in the 50th and 80th percentile (0.031 and 0.037, respectively), and such effects are significant at the 1% level, while for relatively smaller firms – in the 20th percentile – the relationship is positive but non-significant.

Here, we argue that results are consistent with the resource-based view of the firm ([Barney, 1991](#)) since firms' proprietary technologies may represent the source of competitive advantage on the market, hence they reflect a positive effect on investors' expectations which in turn increases the stock value. In contrast, acquisition of external technology does not influence financial performance, since purchased technology is seldom unique, and therefore easily replicable by competitors.

Again, in [Table 8](#) we repeat the same analysis, using the level of employment as the dependent variable.

Results in column (1) show the presence of a positive and significant relationship between development of intangible assets and the level of employment (0.044, p -value < 0.05). A 1% increase in firm's expenditure for development of intangibles creates a 0.044% increase in the number of employees. In contrast, acquisition of intangible assets is not significantly correlated with employment.

In column (2), both explanatory variables are positively and significantly related with the dependent variable at the 1% level, and the effect of development (0.052) is higher than the effect of acquisition (0.027): while both actions increase firm employment, the impact of the former is *vis-à-vis* greater than the latter.

Results in column (3) show that – however – only development appears to be positively and significantly related with the level of employment (0.035, p -value < 0.05). Acquisition, in contrast, has a positive effect on the dependent variable, although it is close to zero (0.007) and non-significant. Quantile distribution shows that the effects of development for relatively smaller groups of firms – 20th and 50th percentile – are positive and significant at the 1% level (0.027 and 0.031, respectively), while for firms in the 80th percentile the effect on employment is non-significant. Acquisition of intangible assets, in contrast, generates positive and significant results on employment across all size classes.

We argue that – in terms of employment – development of resources generates higher returns: when investing creating new technology, companies tend to bring in additional employees to conduct R&D. Instead, when they leverage on the acquisition of

technology, they tend not to increase the number of employees, but rather rely on the firm's absorptive capacity (Cohen & Levinthal, 1990; Denicolai et al., 2016) to integrate the acquired assets.

Summary

Summarizing the results, we see that when controlling for sector-, country-, and year-specific effects, development and acquisition of intangible assets generate different results: both affect the economic side of performance of a firm, measured in terms of turnover. Their effects on the financial and human capital side of performance, however, is different: development of intangible assets generate a positive effect on the level of employment, while acquisition of external intangible assets has a marginally positive effect on financial performance – measured as the value of firm stocks.

Controlling for firm-specific fixed effects, we find a positive and significant effect of both internally developed and external intangible assets. Results are consistent across all models: both variables generate positive results in terms of economic, financial and human capital performance. For all three dimensions, the effect of development is marginally greater than acquisition.

In column (3), we find that both explanatory variables are positively related with firms' economic performance, and that the effects of both variables on turnover is almost equal: a 1% increase in development of intangibles generate a 0.025% increase in turnover, while the same increase in acquisition generates a 0.026% increase. In addition, we find that development of intangible assets is correlated with the other two performance dimensions, while acquisition is not.

Quantile distributions show that acquisition has a positive and consistent correlation among all class sizes with the economic and human capital dimension of performance, while in terms of financial performance the effect is significant only for relatively larger-sized firms (in the 50th and 80th percentile of the sample). Differently, development of assets generates a positive result on economic performance only for relatively larger firms, and a positive effect on the level of employment only for relatively smaller firms, while we find no significant correlation with financial performance.

Discussion

The article builds on OI literature to measure the relationship between the level of openness and firm performance, measured through various dimensions. Results show that the effects of both development and acquisition are positive and significant across different dimensions, but their output varies in terms in magnitude and distribution: both variables are positively and significantly correlated with turnover, and that their effect on the latter is almost equal. In addition, we find that only development is positively and significantly correlated with the other two dimensions of performance, once we control for firm-specific time trends. Once we control for relative size of firms in the sample, we see that the effect of openness is more spread out across different class sizes, while the effect of development of intangibles influences the economic performance only for larger firms, and increases employment only for relatively smaller firms, while it has no effect on the financial side of performance.

Contributions

We argue that the article provides many contributions to existing literature: first, it clarifies the dimensions considered to evaluate the level of openness, the level of performance and the relationship between the two dimensions. Then, it builds on extant literature to overcome existing limitations, proposing the measurement of

inbound openness through the use of objective indicators, the amount invested in the acquisition of externally developed intangible assets and the amount invested by the firm in the development of intangible assets. Such variables provide more reliable indicators of firm propensity to openness than scale measures adopted so far by OI literature (Egbetokun, 2015; Ferreras-Méndez, Newell, Fernández-Mesa, & Alegre, 2015; Laursen & Salter, 2006). In addition, the paper proposes the study of the effects of development versus acquisition on three different dimensions for performance: (1) economic; (2) financial; and (3) human capital.

Limitations

We argue that in this form the paper suffers from three main limitations: first, since it studies the effects of openness versus development using a sample of European companies, it misses out on the behavior of firms from different regions. In addition, since the sample only refers to listed company, we cannot control for smaller-sized firms. Finally, we did not control for the types of intangible assets – whether internal or external – the firms in the sample invest into, therefore missing on sorting out differences among various categories (patents, trademarks, concessions, etc.).

Implications

We believe the article is of interest for both scholars and practitioners. For researchers, the paper provides the basis for overcoming current limitations of OI studies in evaluating the relationship between openness and performance. The inclusion of objective measures of firm propensity for openness – i.e. the level of investment in external intangible assets – provides a more reliable indicator than scale measures derived from secondary data. In addition, the definition of multiple dimensions of performance helps in highlighting the presence of different effects of development versus acquisition across the dimensions.

For managers, we argue that the choice in investing on development of intangibles versus acquisition leads to similar positive results in terms of economic performance, although it seems that the latter is marginally more effective than the former. In contrast, such investments do not directly affect other dimensions such as financial and human capital performance, although we see a marginally significant lagged effect of development on employment.

Further studies

For scholars, the work leaves room for the proposition of similar quantitative studies in different regions, provided that financial data are exhaustive and adopt the same accounting standards across countries. In addition, the inclusion of small- or medium-sized firms could highlight the presence of differences of behavior across size-classes, as posited by previous works (Vrande, de Jong, Vanhaverbeke, & de Rochemont, 2009). Finally, the inclusion of indicators for the amount invested by each company in different intangible asset classes could provide more suitable implications for professionals in the innovation field.
